Such devices include, for example, neurostimulators, pacemakers, defibrillators, insulin pumps, glucose monitors, and cochlear implants. One important use for implantable medical devices is in the treatment of hearing loss. Hearing loss, which may be due to many different causes, is generally of two types, conductive and sensorineural. In some cases, a person suffers from hearing loss of both types. Conductive hearing loss occurs when the normal mechanical pathways for sound to reach the hair cells in the cochlea are impeded, for example, by damage to the ossicles. Conductive hearing loss is often treated by use of conventional hearing aids, which amplify sound so that acoustic information reaches the cochlea and the hair cells. However, such hearing aids have limited ability to restore hearing in noise and in the presence of overlapping speech. In many people who are profoundly deaf, however, the reason for their deafness is sensorineural hearing loss. This type of hearing loss is due to the absence or the destruction of the hair cells in the cochlea which transduce acoustic signals into nerve impulses. These people are thus unable to derive suitable benefit from hearing aid alone, because there is no way to provide a sensory feedback mechanism to drive the auditory nervous system. The cochlea is an organ of the auditory system which lies in the inner ear and is responsible for transducing acoustic signals into auditory nerve impulses. The cochlea contains two types of cells, including auditory hair cells and supporting cells. 2d92ce491b
